We report on the growth method of organic crystals by using organic vapor transport and the electrical characteristics of organic field-effect transistors (OFETs) using the crystal as an active material. The organic crystals such as perylene and rubrene were directly grown from powder by using a continuously flowing N₂ gas in the home-made furnace. In the case of rubrene, the crystal sizes were dependent on the growth time and temperature (see Fig. 1). The crystalline structure of the rubrene and perylene single crystals was characterized by means of a single crystal X-ray diffractometer. In order to place the single crystal onto the Au electrodes of the field-effect transistor pattern, a polymethylymethacrylate thin layer was spin-coated on top of the crystal surface. The OFETs using rubrene or perylene single crystal showed a typical p-type operating mode.
